Young Embedded Clusters and the Birth Environment of the Solar System

SOFIA Community Task Force Teletalk 30 June 2010 -- Fred C. Adams

[A. Bloch, M. Fatuzzo, J. Ketchum, D. Hollenbach, G. Laughlin, P. Myers, and E. Proszkow]

Most Stars Form in Clusters:

[1] How does the initial cluster environment affect the formation of stars and planets?

[2] What were the basic properties of the birth cluster of our own Sun and its Solar System?

TIME SCALES

Infall-Collapse Timescale = 0.1 Myr

Embedded Cluster Phase = 3 - 10 Myr Circumstellar Disk Lifetime = 3 - 10 Myr Giant Planet Formation Time = 3 - 10 Myr

Terrestrial Planet Formation = 100 Myr Late Heavy Bombardment = 600 Myr Open Cluster Lifetime = 100 - 1000 Myr

Cumulative Distribution: Fraction of stars that form in stellar aggregates with N < N as function of N

CONJECTURE:

The cluster environment affects planet formation much more than the process of star formation

Why: Clusters have radial scale of 1 pc, with distance between protostars of 0.24pc. Cores are observed to move at 0.1 km/s. During their formation time of 0.1 Myr, protostars move only 0.01 pc << 0.24 pc...

Dynamical Studies

- I. Evolution of clusters as astrophysical objects
- II. Effects of clusters on forming solar systems (with a focus on our own system)
 - Distribution of closest approaches
 Radial position probability distribution

Simulations of Embedded Clusters

- Modified NBODY2(and 6) Codes (S. Aarseth)
- Simulate evolution from embedded stage to age 10 Myr
- Cluster evolution depends on the following:
 - cluster size
 - initial stellar and gas profiles
 - gas disruption history
 - star formation history
 - primordial mass segregation
 - initial dynamical assumptions
- 100 realizations are needed to provide robust statistics for output measures

(E. Proszkow thesis 2009)

Closest Approach Distributions

Simulation	Γ_0	γ	b _c (AU)
100 Subvirial	0.166	1.50	713
100 Virial	0.0598	1.43	1430
300 Subvirial	0.0957	1.71	1030
300 Virial	0.0256	1.63	2310
1000 Subvirial	0.0724	1.88	1190
1000 Virial	0.0101	1.77	3650

Typical star experiences one
close encounter with impact0.0010parameter b_C during time10 Myr0.0010

SOFIA can help determine Initial Conditions: Positions, Masses, & Velocities for clumps (results shown here for NGC1333)

Solar System Scattering

3. Parameters describing a (circular) planetary orbit: $r, \theta_1, \theta_2, \theta_3$

Monte Carlo Experiments

- ***** Jupiter only, v = 1 km/s, N=40,000 realizations
- ***** 4 giant planets, v = 1 km/s, N=50,000 realizations
- *** KB Objects, v = 1 km/s, N=30,000 realizations**
- ***** Earth only, v = 40 km/s, N=100,000 realizations
- ★ 4 giant planets, v = 40 km/s, Solar mass, N=100,000 realizations
- * 4 giant planets, v = 1 km/s, varying stellar mass, N=100,000 realizations

Red Dwarf Captures the Earth!

Scattering Results for our Solar System

Cross Sections vs Stellar Mass

Effects of Cluster Radiation on Forming/Young Solar Systems

- Photoevaporation of a circumstellar disk
- Radiation from the background cluster often dominates radiation from the parent star (Johnstone et al. 1998; Adams & Myers 2001)
- FUV radiation (6 eV < E < 13.6 eV) is more important in this process than EUV radiation
- FUV flux of G₀ = 3000 will truncate a circumstellar disk to r_d over 10 Myr,

where

Composite Distribution of FUV Flux

FUV Flux depends on:

- Cluster FUV luminosity
- Location of disk within cluster

Assume:

- FUV point source at center of cluster
- Stellar density $\rho \sim 1/r$

G₀ Distribution

Median	900
Peak	1800
Mean	16,500

Photoevaporation Model

(Adams et al. 2004)

Results from PDR Code

Solution for the Fluid Fields

outer disk edge

Evaporation Time vs FUV Field

(for disks around solar mass stars)

Evaporation Time vs EUV Field

(FUV radiation has larger effect on solar nebula than EUV)

Evaporation Time vs Stellar Mass

Evaporation vs Accretion

Conclusion [1]

Clusters have a moderate effect on the solar systems forming within them -- environmental effects are neither dominant nor negligible:

Closest approaches of order 1000 AU Disks truncated dynamically to 300 AU Disks truncated via radiation to 40 AU Lifetimes have environmental upper limit Planetary orbits are moderately altered Only a few planetary ejections per cluster

(these effects must be described via probabilities)

Where did we come from?

Solar System Properties

Enrichment of short-lived radioactive nuclear species

Planetary orbits are well-ordered (ecc. & inclination)

Edge of early solar nebula -- gas disk -- at 30 AU

Observed edge of Kuiper belt at around 40 - 50 AU

Orbit of dwarf planet Sedna: e = 0.82 and p = 70 AU

Short-Lived Radio Isotopes

Nuclear Species	Daughter	Reference	Half-life (Myr)	Mass Fraction
⁷ Be	⁷ Li	⁹ Be	53 days	(8 × 10 ⁻¹³)
¹⁰ Be	¹⁰ B	⁹ Be	1.5	(10 ⁻¹³)
²⁶ AI	²⁶ Mg	²⁷ AI	0.72	3.8 × 10 ⁻⁹
³⁶ CI	³⁶ Ar	³⁵ CI	0.30	8.8 × 10 ⁻¹⁰
⁴¹ Ca	⁴¹ K	⁴⁰ Ca	0.10	1.1 × 10 ⁻¹²
⁵³ Mn	⁵³ Cr	⁵⁵ Mn	3.7	4.0 × 10 ⁻¹⁰
⁶⁰ Fe	⁶⁰ Ni	⁵⁶ Fe	1.5	1.1 × 10 ⁻⁹
¹⁰⁷ Pd	¹⁰⁷ Ag	¹⁰⁸ Pd	6.5	9.0 × 10 ⁻¹⁴
¹⁸² Hf	¹⁸² W	¹⁸⁰ Hf	8.9	1.0 × 10 ⁻¹³

Solar Birth Requirements (1.0)

Supernova enrichment requires large N

Well ordered solar system requires small N

Probability of Supernovae

Cross Section for Solar System Disruption

Expected Size of the Stellar Birth Aggregate

Adams & Laughlin, 2001, Icarus, 150, 151

Constraints on the Solar Birth Aggregate

(1 out of 60)

(Adams & Laughlin 2001 - updated)

Extended Constraints

SEDNA: Orbit can be produced via scattering encounter with b = 400 - 800 AU. Need value near lower end to explain edge of Kuiper Belt (Kenyon, Bromley, Levison, Morbidelli, Brasser)

RADIATION: FUV radiation field G < 3000. Implies constraint on available real estate in Birth Cluster (will be function of size N)

Extended Constraints

[2] The Solar Birth Aggregate Cluster size: N = 1000 - 7000

Reasonable *a priori* probability (few percent)

Allows meteoritic enrichment and scattering survival

UV radiation field evaporates disk down to 30 AU

Scattering interactions truncate Kuiper belt at 50 AU leave Sedna and remaining KBOs with large (a,e,i)

Disk Truncation Radii due to SN Blast

Timing and Tuning Issues

[1] The 25 Msun SN progenitor lives for 7.5 Myr, solar nebula must live a bit longer than average. [2] Solar system must live near edge of cluster for most of the time to avoid radiation, but must lie at distance of 0.1 - 0.2 pc at time of explosion. [3] Solar system must experience close encounter at b = 400 AU to produce Sedna, but no encounters with b < 225 AU to avoid disruption of Neptune, etc. [4] Solar system must live in its birth cluster for a relatively long time (100 Myr), a 10 percent effect.

Constraint Summary

Solar System Property	Implication	Fraction
Mass of Sun	M ≥ 1M	0.12
Solar Metallicity	Z ≥ Z	0.25
Single Star	(not binary)	0.30
Giant Planets	(successfully formed)	0.20
Ordered Planetary Orbits	N ≤ 10 ⁴	0.67
Supernova Enrichment	N ≥ 10 ³	0.50
Sedna-Producing Encounter	$10^3 \le N \le 10^4$	0.16
Su cient Supernova Ejecta	d ≤ 0.3 pc	0.14
Solar Nebula Survives Supernova	d ≥ 0.1 pc	0.95
Supernova Ejecta and Survival	0.1 pc ≤ d ≤ 0.3 pc	0.09
FUV Radiation A ects Solar Nebula	G ₀ ≥ 2000	0.50
Solar Nebula Survives Radiation	$G_0 \le 10^4$	0.80

Alternative Scenarios for Nuclear Enrichment

[1] Internal enrichment -- X-wind models (Shu et al.)
[2] AGB stars -- low probability (Kastner, Myers)
[3] WR stars -- also low probability (need m > 60)
[4] Distributed enrichment (Gounelle)
[5] Supernova enrichment with varying progenitors

[a] Need some combination: Stellar source for 60Fe, spallation for 7Be and 10Be, both for 26AI...
[b] Sedna constraint almost same as SN constraint, so prediciton for solar birth aggregate unchanged

Conclusions:

[1] Initial cluster environment has moderate effect on disks and planets (less effect on star formation itself)

[2] Birth aggregate of Solar System was a moderately large cluster with stellar membership N = 4000 + 2000

Possible Roles for SOFIA

 Measure initial conditions for Star Formation in clusters (nearby regions)
 Help determine distribution of embedded cluster sizes/masses (farther regions)
