

Synergies in Spectroscopy between SOFIA and the Ground:

Ulli Käufl,

Ringberg Workshop on Spectroscopy with SOFIA March 16, 2015

Background Noise Limit:

"Observing at 10μm has been likened to observing visually through a telescope lined with luminescent panels and surrounded by flickering light as though the telescope were on fire"

Low & Rieke, 1974

note:

2014: this should read:
"Observing > 2.3μm ..."

WILH. HERSCHEL.

Outline

- wavelength range λ : 3-13.3 μm
- mostly high resolution work: $\lambda/\Delta\lambda > 30.000$
 - no science case for ground based medium resolution spectroscopy
 - low resolution work still interesting in N-band for SEDs / dust
- focus on facility instrumentation, hence mostly about ESO VLT instrumentation
 - VLT-CRIRES $\lambda/\Delta\lambda \leq 100.000$ λ : 3-5.5 μm encompasses Keck HIRES
 - VLT-VISIR $\lambda/\Delta\lambda \sim 500$ and 30.000 only facility world wide but PI instruments exist
- spectro astrometry, a spatial super resolution technique

spectroscopy: enhancing what you want to see

- example: [Ne II] at 12.83 μm , contamination with H_2O pwv 5, 2.5 and 1mm
- spectra from ESO skycalc tool

- message 1: only if you resolve **telluric** lines can one correct
- message 2: it may pay off to wait for pwv to fall

Monitoring of precipitable water vapour at observatory

- introduced at VLT in 2012 as part of the VISIR upgrade
- commercial fully automated radiometer with IR channel for sky brightness to monitor thin clouds (Kerber et al 2012)
- carefully cross-calibrated with radio sondes and Echelle spectroscopy from 500-5000 nm
- the ESO-VLT is operated in <1 hour time slices: the pwv-value is now a scheduling criterion, user specified, equivalent to the seeing

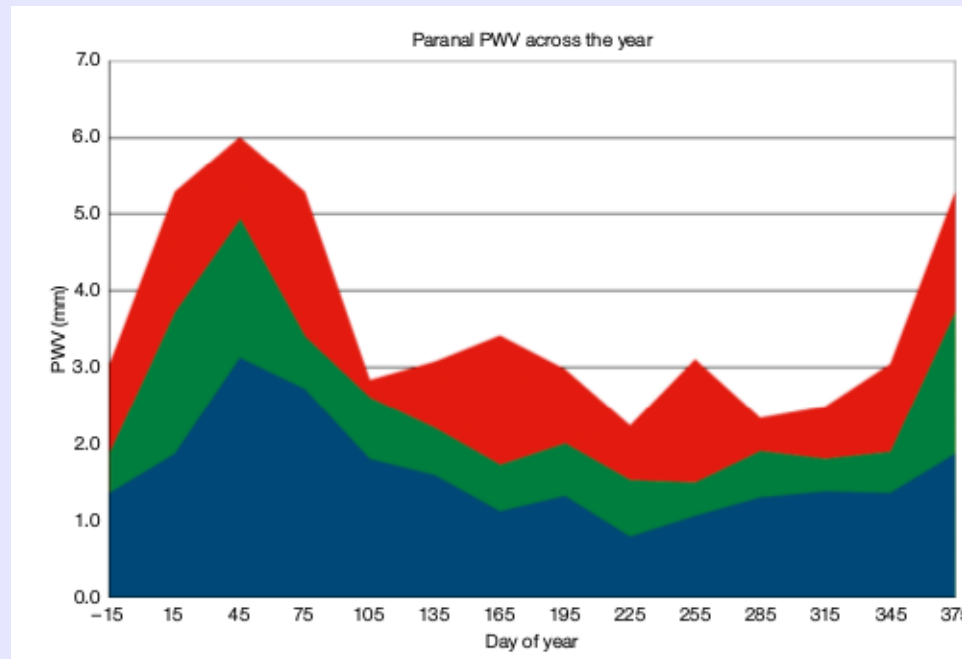

Figure 5. PWV conditions over Paranal based on the analysis of about a decade of UVES data (Kerber et al., 2010a). A pronounced seasonal variation is evident, but very low PWV (< 1.5 mm) conditions are available at the 25 % level for most of the year.

■ 75% quartile
■ 50% quartile
■ 25% quartile

The right spectral resolution?

irrespective of width of spectral features
in astronomical object, **what counts is
rejecting telluric features**

ESO offers sophisticated LBLRT atmospheric calculator

[https://www.eso.org/observing/etc/bin/gen/form?
INS.MODE=swspectr+INS.NAME=SKYCALC](https://www.eso.org/observing/etc/bin/gen/form?INS.MODE=swspectr+INS.NAME=SKYCALC)

c.f Noll et al, A&A 2012 & Jones et al, A&A 2013

- explicitly calculating the annular Doppler shift modulation

LBLRT Quality Check

- measured vs. calculated K-band spectra c.f. Seyfahrt and Käufel, A&A 2008?

An Example from M-Band

- an example of radiance in the region of the CO fundamental band, Paranal vs 5050m

Don't forget shotnoise ...

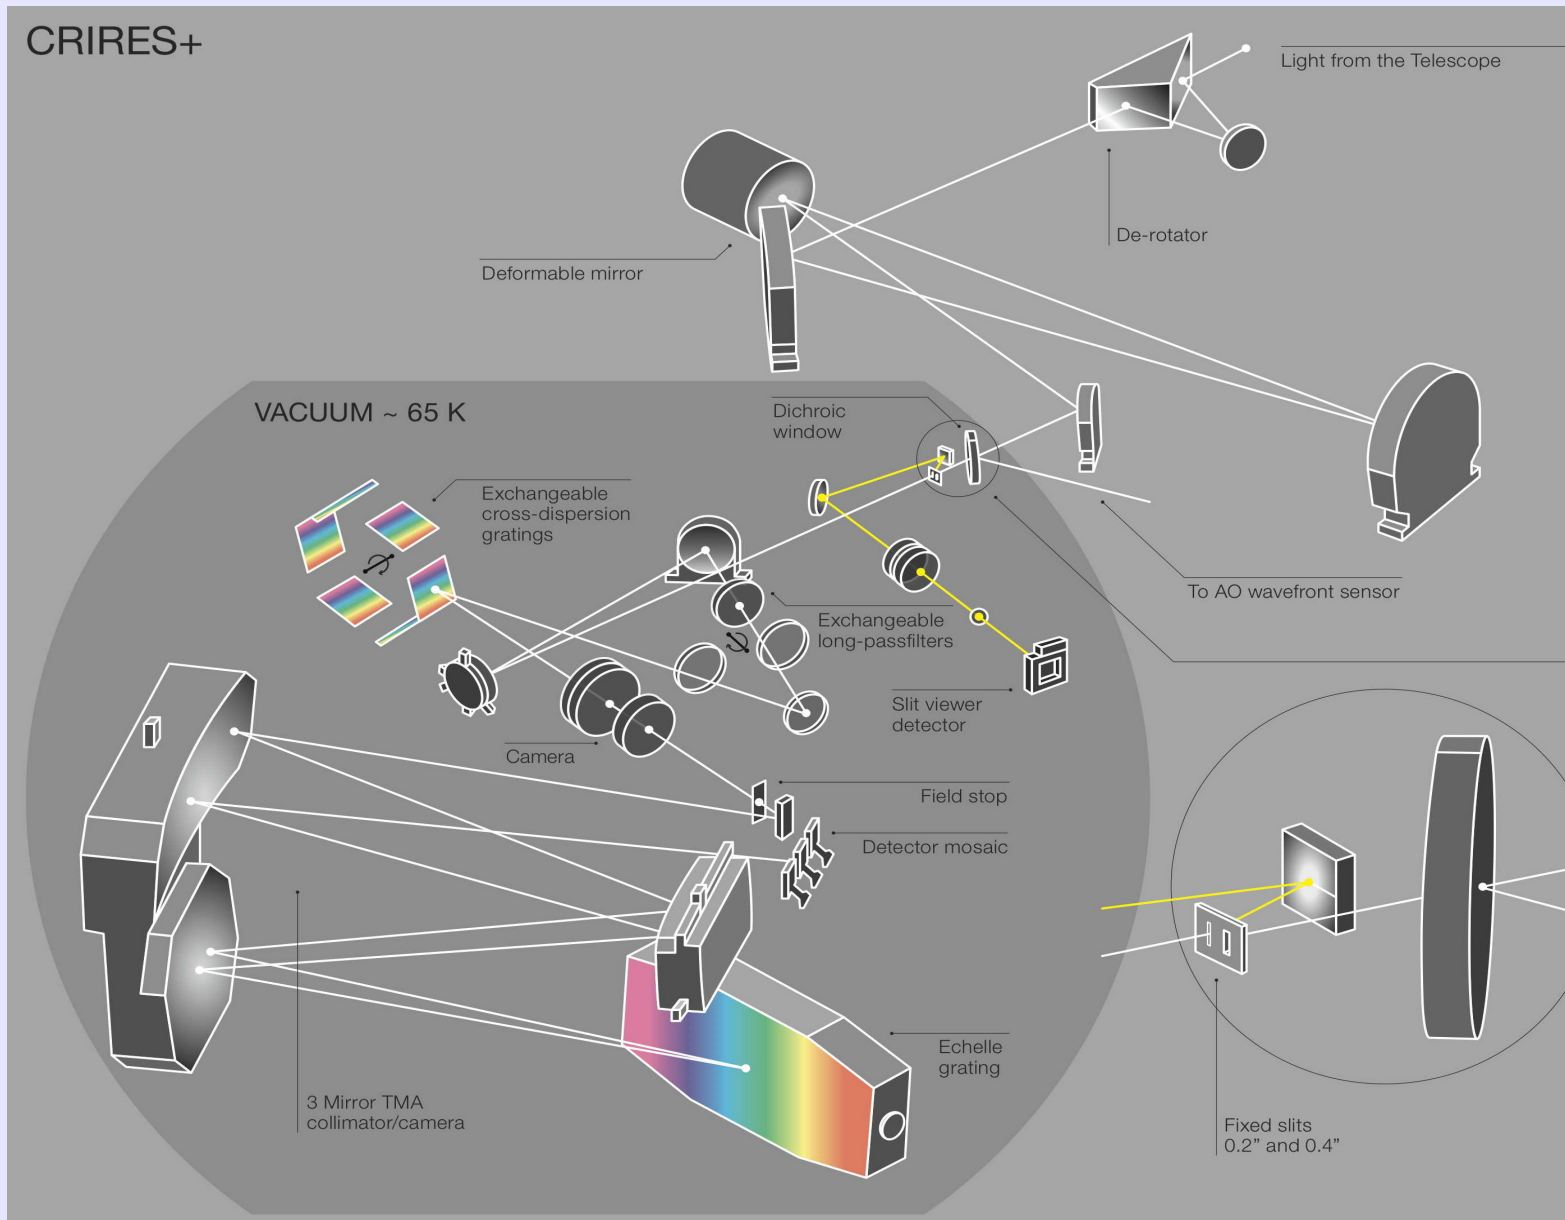

- detector noise and dark current are basically negligible for modern HgCdTe detectors up to $\lambda \lesssim 5500$ nm
- internal background and dark current also negligible:
 - VLT-CRIFRES: DC $< 1/20^{\text{th}} e^-$
 - VLT-VISIR: DC $< 200 e^-$
- dominant back-ground sources
 - thermal radiation of telescope and warm optics
 - line radiation of infrared active atmospheric trace species H_2O , CO , CO_2 , CH_4 , N_xO_y , OCS
 - shot noise of the source: high dispersion projects often require $s/n \gtrsim 100$
needs $10^4 e^- \Rightarrow \text{noise} \sim 100 e^-$

historic CRIRES,
now
being upgraded:
new detectors
x-dispersed

CRIRES+

Schematics of CRIRES

after the upgrade, 2017 the old pre-disperser will be replaced by a set of x-dispersion gratings

CRIRES

main characteristics

- **frequency coverage:** $\nu \sim 58.000 - 310.000 \text{ GHz}$ ★
($\lambda \sim 950 - 5200 \text{ nm}$)
- **spectral resolution:** $\nu / \Delta\nu$ ($\lambda / \Delta\lambda$) $\approx 10^5$ or
 $\Delta\nu \approx 3 \text{ km/s}$
(2 pixel Nyquist sampling)
- **array detector mosaic:**
4 x 1024 x 512 Aladdin III InSb mosaic
☞ instantaneous ν - coverage $\sim 2.0 \%$
pixel scale 0.1"/pix
- **infrared slit viewer** (Aladdin III) with J,H & K-filters
- **precision** for calibration and stability $\sim 75 \text{ m/s}$
i.e. $1/20^{\text{th}}$ of a pixel or 5 mas tracking error
- **self-aligning spectrograph:** piezo vernier alignment

CRIRES

main characteristics (cont)

- spectrograph **intrinsic stability** $\ll 75\text{m/s}$
preference in design was given to stability
 - ☞ gas cells for high precision radial velocity work and absolute frequency calibration
- curvature sensing **Adaptive Optics**
 - ☞ 0.05" spatial resolution per pixel in slit siewer camera
 - right:** composite JHK false color image the Jovian satellite Io (dia 1.1")
- **spectro-polarimetry in lines:**
 - after upgrade
 - magnetic fields
 - exo-planet atmospheres
 - goal to measure all 4 Stokes parameter

M-band highlight spectro-astrometry

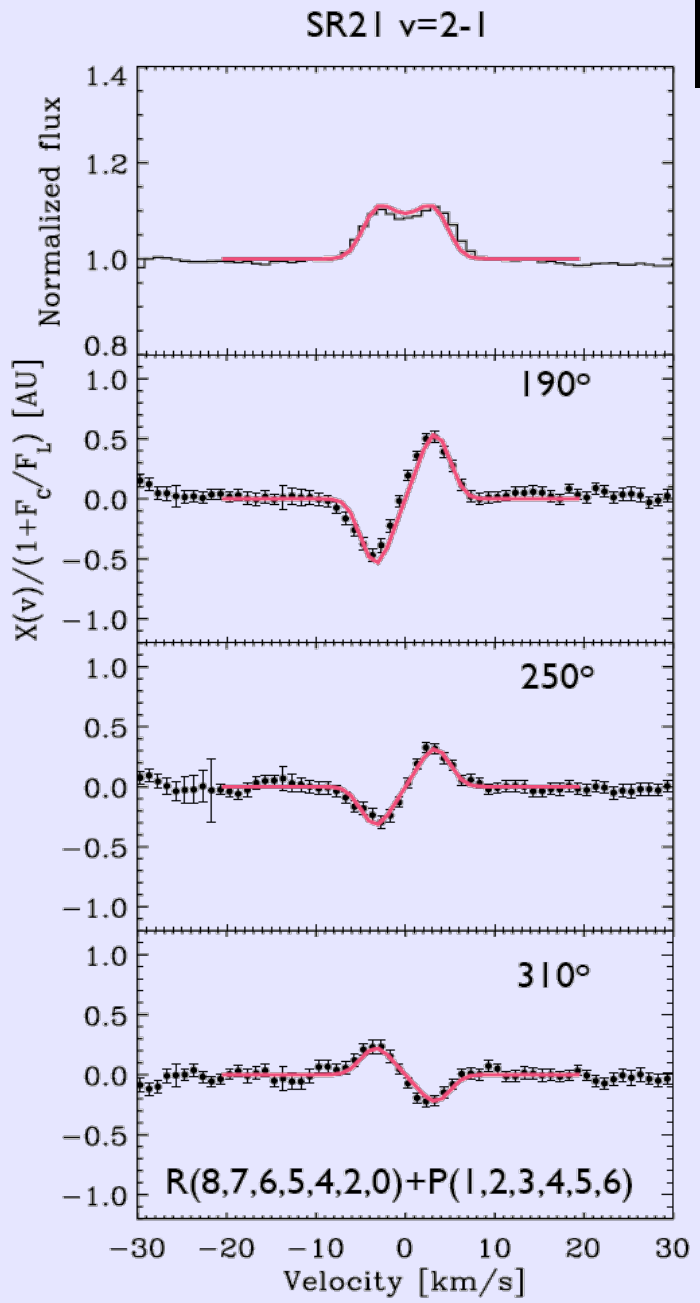

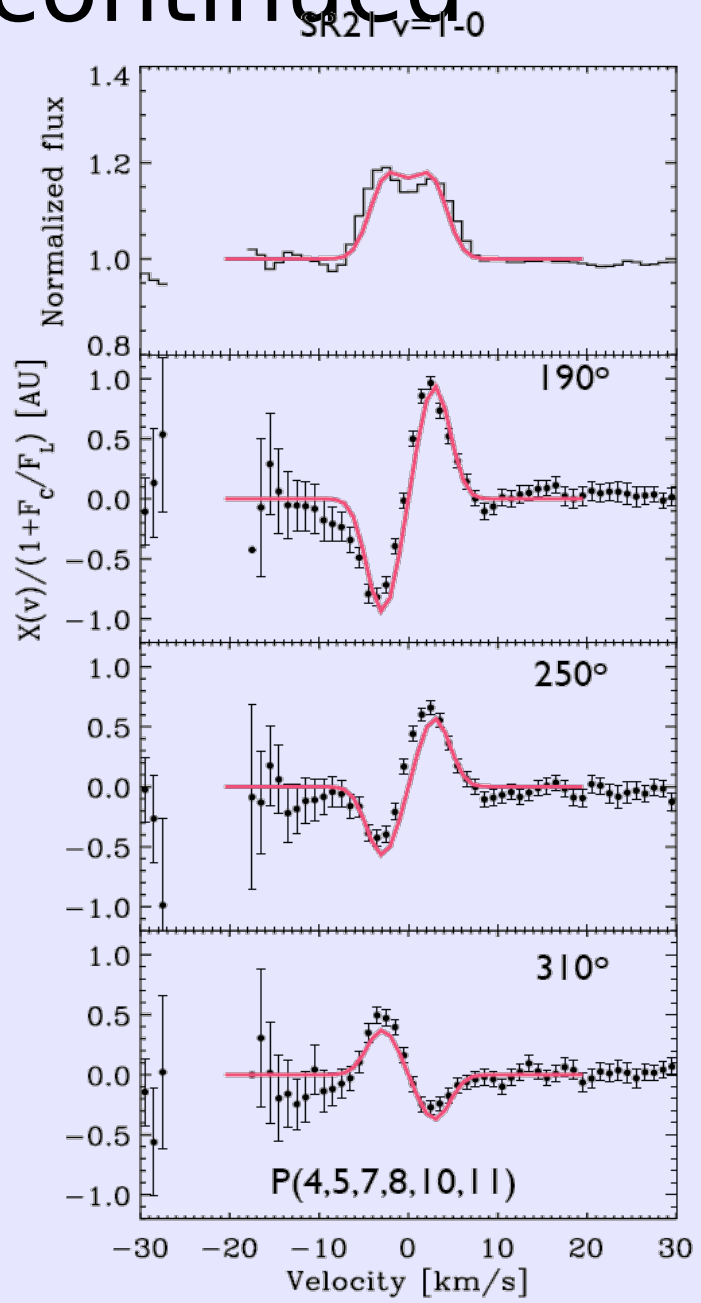

$^{12}\text{CO} / ^{13}\text{CO}$
profiles of a
disk with
known inner
hole
(SR 21)

(Pontoppidan
et al. ApJ
2008)

FIG. 1.— A small section of the spectral range covered for SR 21 showing the flux spectrum (*top*), the atmospheric transmission spectrum (*middle*) and the spectro-astrometric signal (*bottom*). The units on the vertical axis are in pixels, relevant for the spectro-astrometric signal; the other two curves are scaled for clarity. The emission lines in the $v = 1 - 0$ rovibrational band (unless otherwise indicated) intrinsic to the SR 21 disk are marked with vertical dashed lines.

Spectro-astrometry continued

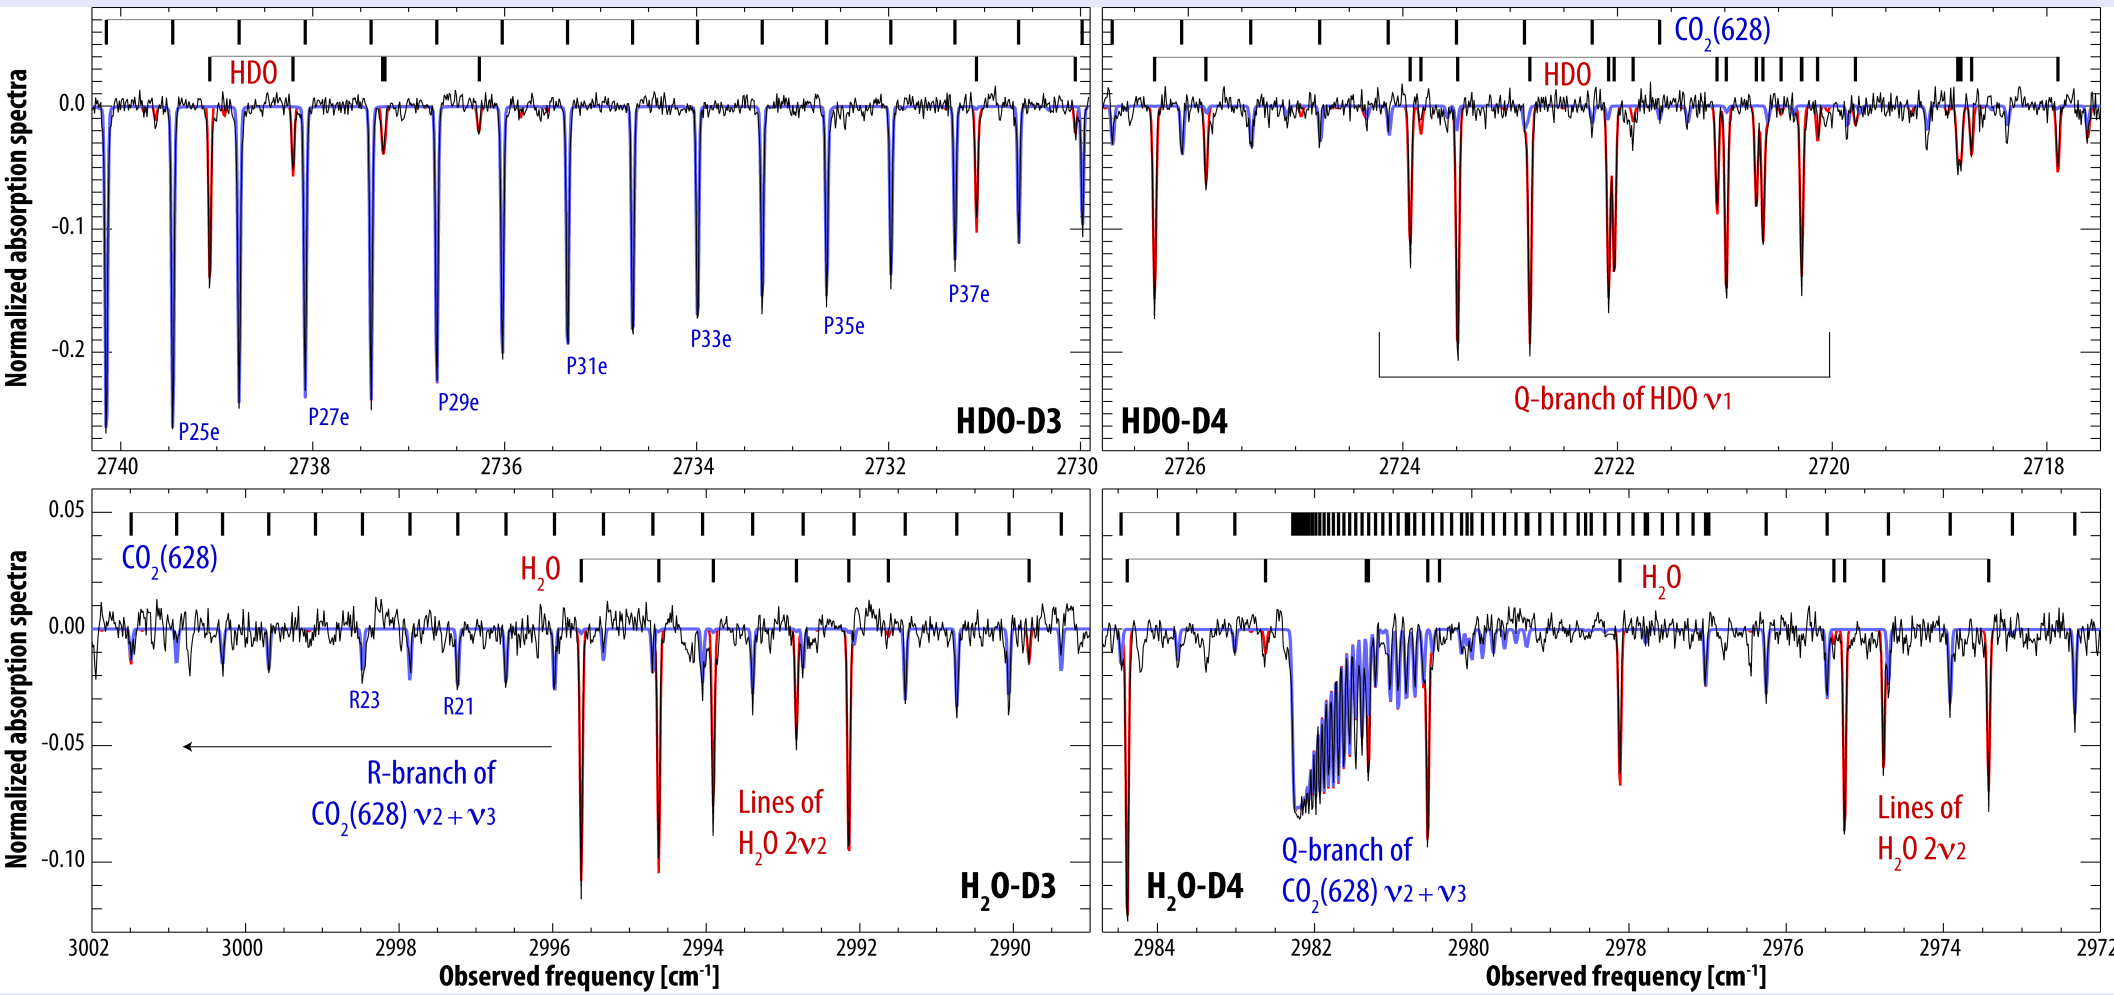

^{12}CO fundamental band, all rotational lines averaged

spectro-astrometric signature as a function of Doppler velocity for three slit position angles

note:
 spatial resolution ~ 0.1 AU
 (< 1 mas) !!!!
 (Pontoppidan et al. ApJ 2008)

D/H, another scientific highlight here Mars

- typical spectrum, Mars VLT-CRIRES
- 6 years of data, Villanueva et al, Science 2015

- D/H enrichment up to 10 relative to VSMOW found
- suggests existence of ocean >1km on Mars

Frequency calibration with telluric lines: CRIRES

- SiO overtone in MS-Vel vs telluric N_2O allowed for a frequency calibration / stability of 20m/s (Seifahrt&Käufl A&A, 2008)
- using the ESO-UVES archive Figueroa et al, A&A, 2010 showed that telluric lines intrinsically allow for spectral calibrations to the 5-10m/s level

What about SEDs?

- 3-5.5 μm :
 - after the CRIRES upgrade both the L and M-band can be covered with ~ 6 exposures at $\lambda/\Delta\lambda \sim 10^5$
 - as telluric features are adequately resolved, they can be fully accounted for
 - rebinning of data with statistic weights will yield data far superior to low resolution work

note (Dan Jaffe):

*you cannot be too thin, you cannot be too rich
and you cannot have too much spectral resolution*

- 7.7-13.3 μm to be continued with VISIR

VISIR at the VLT: Overview

- built by CEA/Astron, upgraded by ESO
- 10/20 μm imager/spectrometer ($R \sim 500 - 30.000$)
- sensitivity (BLIP)
~ 2mJy 10 μm imaging
~ 40-1000mJy spectro
- diffraction limited (FWHM $\sim 0.3''$ sampling 0.045" / pix)
- as of Nov 2014 back @ VLT-UT3

schematics of VISIR spectrograph

- two collimators
- low, medium and high resolution modes
- 8-13 μm in one exposure with prism ($\lambda/\Delta\lambda \sim 500$)
- 7.7-13.3 μm Echelle mode ($\lambda/\Delta\lambda \sim 30.000$)
general: x-dispersed
selected lines: long slit mode

close-up ZnSe prism on low-res carousel

Why a prism?

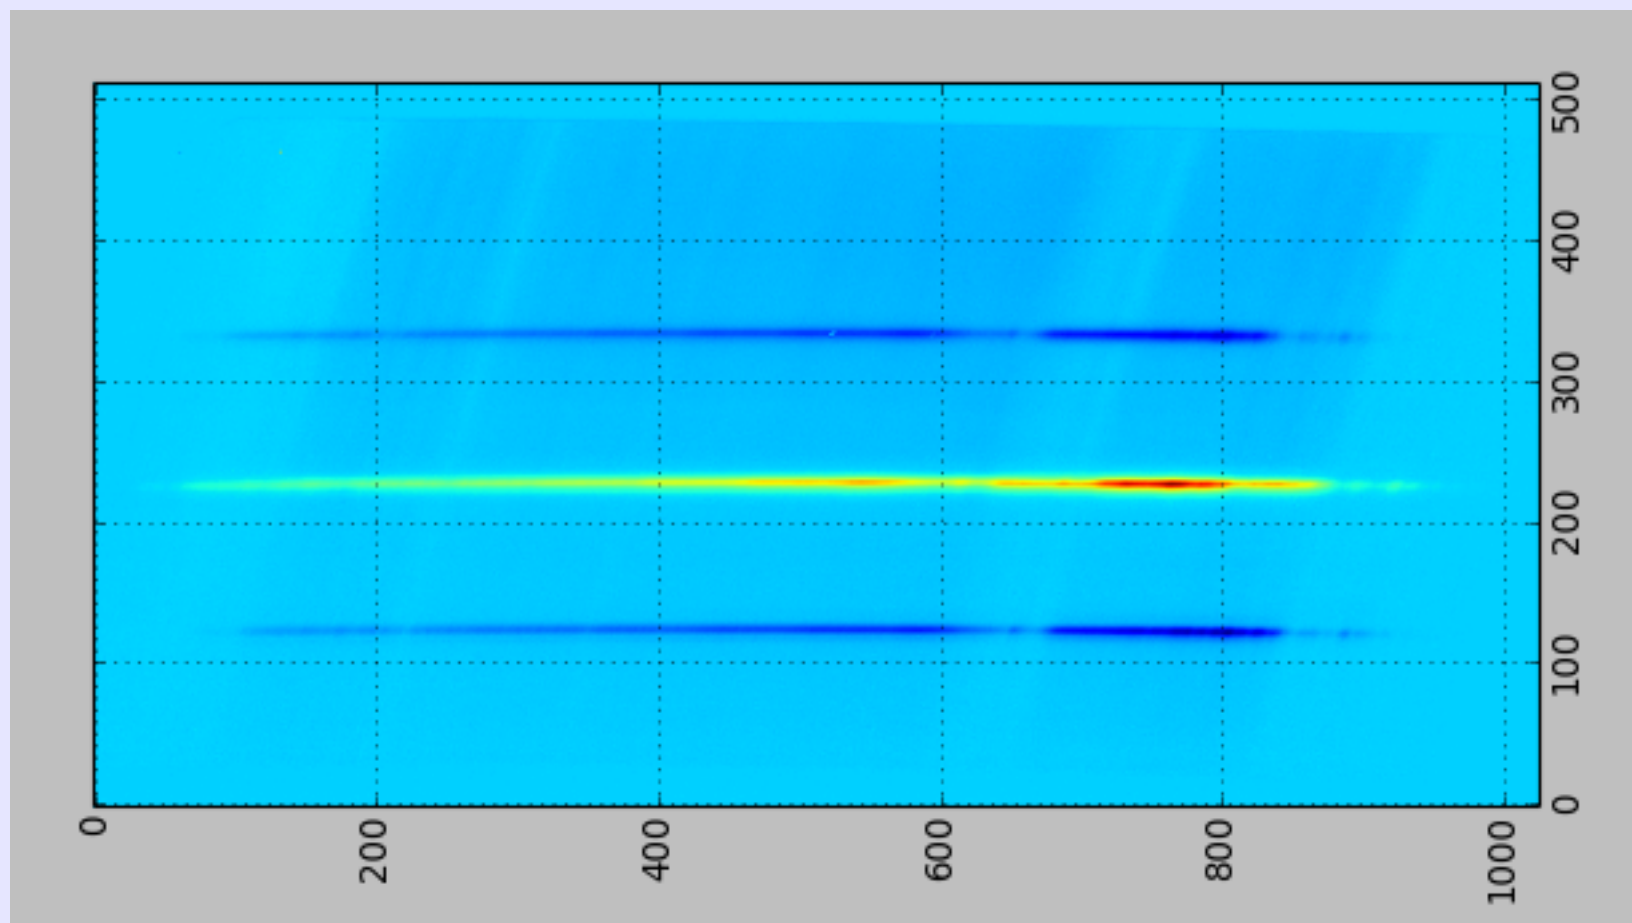

ZnSe prism gives complete N-band in one exposure
=> 4 fold more efficient than "old" VISIR

$\lambda/\Delta\lambda$: 300-500
no filter etc => highest throughput

and
straylight by design minimized

VISIR upgrade

low resolution prism mode

- standard star spectrum spanning 23.000GHz to 39.000GHz (vulgo 7.7 to 13.3 μ m)

VISIR low resolution sensitivity

- i.e. a factor of 2 improvement to old VISIR, while 4 times faster!
- VISIR spectroscopy now as good as TIMMI2 imaging was

spectro-astrometry: the SED case

R. van Boekel et al.: Extended mid-IR emission in Herbig Ae/Be stars

179

left:
circum-stellar material
observed with the ESO
3.6m telescope around
a Herbig AeBe star at a
spatial scale of $1/5^{\text{th}}$
of a pixel, here 0.1'' **note:**
this corresponds to a
 $\sim 330\text{m}$ interferometric
baseline (van Boekel et
al. 2004, A&A **418**,
177)

How does it work?

differential method, using shape of the cross-dispersion profile as a PSF proxy to deconvolve the spectrum in spatial direction in an adjacent wavelength interval (similar to spectral differential imaging SDI)

VISIR upgrade, small excursion to imaging

- left linear, right logarithmic (burst mode)
- green bar 1 arcsec

VISIR Echelle Sensitivity

example at $\lambda \sim 12.8 \mu\text{m}$

- at least a 40-60% improvement, while 2 times faster!
- preliminary, set-up and pipeline not tuned

VISIR Spectrograph 1st Light

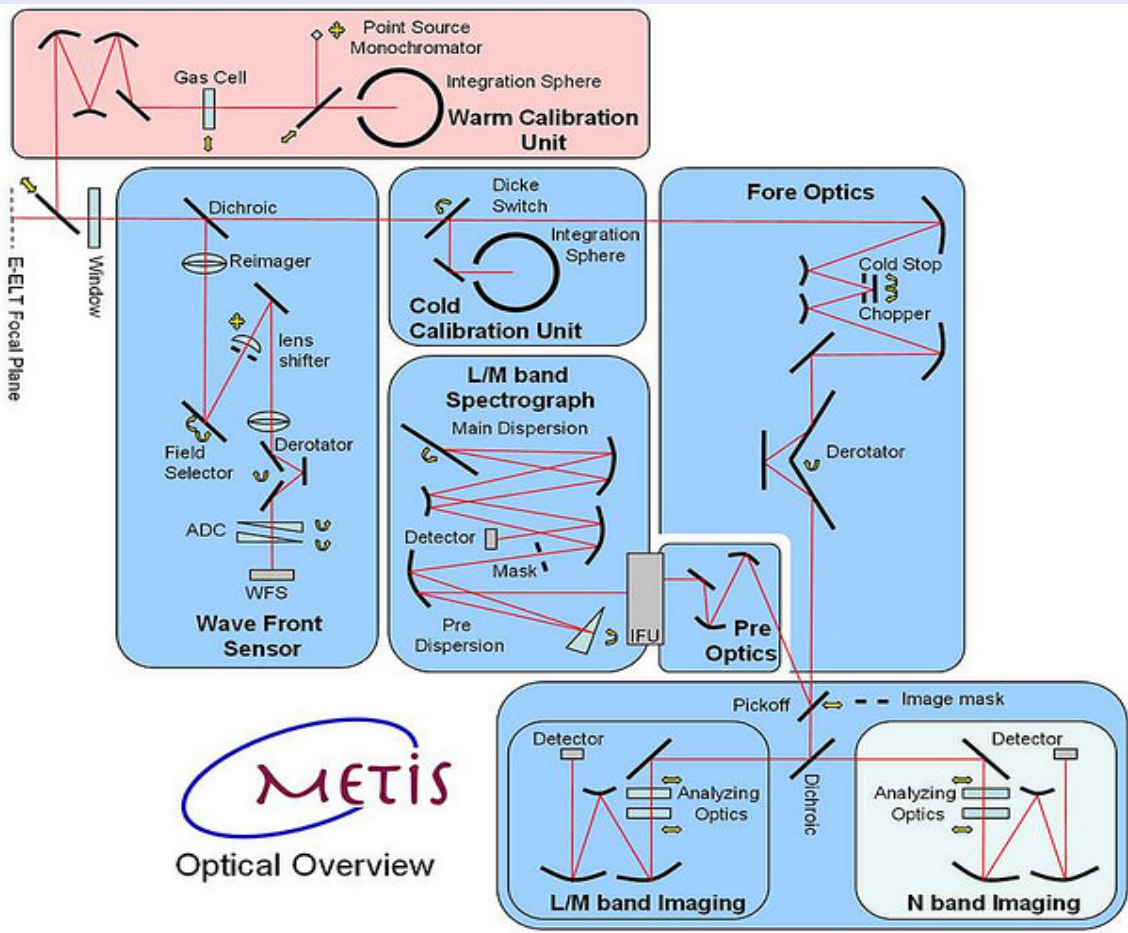

- more 1st light results
Menzel 3 [Ne II], $\lambda \sim 12.8\mu\text{m}$
- long-slit spectroscopy
 $R \sim 30000$ (i.e. 10 km/s)

- note: in BLIP (back-ground noise limited performance) $S/N \propto \sqrt{R}$

Outlook: E-ELT-METIS

- E-ELT, 38m,
Cerro Armazones 3064m vs 2634m
- METIS is CRIRES-red and VISIR-blue
<http://metis.strw.leidenuniv.nl/index.php>

Conclusions

- many spectral lines only accessible for SOFIA
- Q-band on average much better from SOFIA
- global SEDs better from SOFIA
- specific lines in windows always better from the ground, even when only marginally possible
- spatial information from ground unsurpassed
 - 8m vs 2.5m
 - super-resolution techniques
- flexibility in scheduling and PWV monitoring allow for sensitive ground based synoptic observations
- SOFIA and ground based telescopes thus “orthogonal”
- SOFIA to prepare the Q-band science case for the E-ELTs

DON'T PANIC
